

94-0039

The invention relates to the cigarette and filter production used into them.

The technical purpose of the invention consists in reducing the outlet of nicotine in the secondary smoking vein. The elongated cigarette having an equal cross section along its full length contains a filter and a cover of cigarette paper consisting of the first cigarette paper layer that wraps the tobacco filling and the second layer that wraps the first one. The weight in gr/m_l of the cigarette paper of the second layer exceeds the cigarette paper weight of the first layer and the cigarette circumference length constitutes 17 mm. The second layer of the cigarette paper contains a solid filling, particularly chalk. The density of the tobacco filling pressing is of 293 mg/cm³ and the filling stipe length is of 70 mm where the filter length constitutes 27 mm. The filling content constitutes 29%.
