

99-0077

The invention relates to the medicine, in particular to the obstetrics and is used for prophylaxis of puerperal endometritis.

The proposed method consists in the administration of a suspension of mononuclear cells culture, obtained from the recipient blood, paracervically in the first 24...48 hours in the puerperium in a single dose of 2 ml.

The result of the invention consists in the immunostimulating action and reduction of endogenic intoxication.
