

99-0165

The invention relates to medicine, particularly to surgical oncology and may be applied for surgical treatment of breast cancer located in the external sectors.

Summary of the invention consists in the fact that two incisions of transversally oval shape are executed, covering the tumor and mamelono-areolar zone, starting in the same place from the medium axillary line and directing towards the sternum. The upper incision, not reaching 7...10 cm up to the sternum is directed parallel to the sternum towards the submammary plica and not reaching 2...4 cm up to the submammary plica it is joined with the lower incision forming a curve in its direction. Then follows the tumor extirpation being in block with the lymphatic collectors of subclavicular, subscapular and axillary zones. After that the wound is sutured and actively drained.
