The invention refers to medicine, in particular to surgery and may be used for plasty of recidivating direct and indirect inguinal hernias.

Summary of the invention consists in that it is carried out excision in the form of arch of the skin and of the subcutaneous tissue, upwards with 1 cm and parallel to the fallopian ligament, then it is opened the abdominal canal and lifted up the funicle or the round uterus ligament, it is mobilized the hernial sac, it is ligated the cervix and it is excised. After removal of the hernial sac it is carried out plasty of the posterior wall of the abdominal canal with local remaining tissues. Afterwards, it is prepared anautodermal flap which is sutured to the above aponeurosis of the internal oblique muscle of abdomen, medially and below to the Gimbernati (pectineal) ligament and to the remaining cicatricial tissues of the fallopian ligament. At the same time, in the lateral part of the abdominal canal, the flap is sutured to the anterosuperior iliac spine, and from the lateral edge of the flap it is modeled a new internal abdominal ring. After application of the skin flap it is reduced the funicle or the round uterus ligament and it is made the anterior wall duplicate of the abdominal canal, and then it is sutured the skin and the subcutaneous tissue.
