The invention refers to medicine, in particular to the stomatologic equipment and may be used for gum formation before fixation of dental prostheses.

Summary of the invention consists in that the device is consisted of a body with a longitudinal channel with thread in the middle and a screw for fixation to the implant. The body is made cylindrical in the upper part, with a height of 2,0...7,0 mm, with circular grooves made onto its external surface, and the lower part is made in the form of hexagonal prism with a smaller diameter, the parts being joined between them by means of a truncated section. The screw includes a head of cylindrical shape with a recess in the form of hexagon and a threaded rod at the free end. At the same time, the section of the channel in the upper part of the body is made as socket for the screw head.
